EXP NO: 7	GENERATIVE MODELS WITH GANS: CREATING AND TRAINING A GENERATIVE ADVERSARIAL NETWORK

AIM:
To construct and train a Generative Adversarial Network (GAN) using the TensorFlow/Keras framework. The objective is to train the GAN on the MNIST dataset to generate new, synthetic images of handwritten digits that are indistinguishable from the original training data.

ALGORITHM:
Generative Adversarial Networks (GANs)
GANs are a class of generative models that learn a training distribution by pitting two neural networks against each other in a zero-sum game: a Generator and a Discriminator.

1. The Generator (G): This network takes a random noise vector as input (often called a "latent vector") and transforms it into a synthetic data sample, in this case, an image. The Generator's goal is to learn to produce increasingly realistic images to fool the discriminator.

2. The Discriminator (D): This is a binary classifier network. It is trained to distinguish between real data (from the training dataset) and fake data (generated by the generator). Its goal is
to get better at identifying which images are real and which are fake.

3. The Adversarial Process:
Step A (Training the Discriminator): The discriminator is trained on a batch of both real images (labeled as "real" or 1) and fake images from the generator (labeled as "fake" or 0). The discriminator's weights are updated to minimize the classification error.
Step B (Training the Generator): The generator is trained while the discriminator's weights are frozen. The generator creates fake images and feeds them to the discriminator. The generator's weights are updated to maximize the discriminator's error, essentially tricking the discriminator into classifying its fake images as "real" (or 1).

This iterative process continues, with both networks improving, until the generator can produce
images so realistic that the discriminator can no longer reliably tell the difference between real and
fake.

CODE:

```
# Import necessary libraries
import numpy as np
import matplotlib.pyplot as plt

```
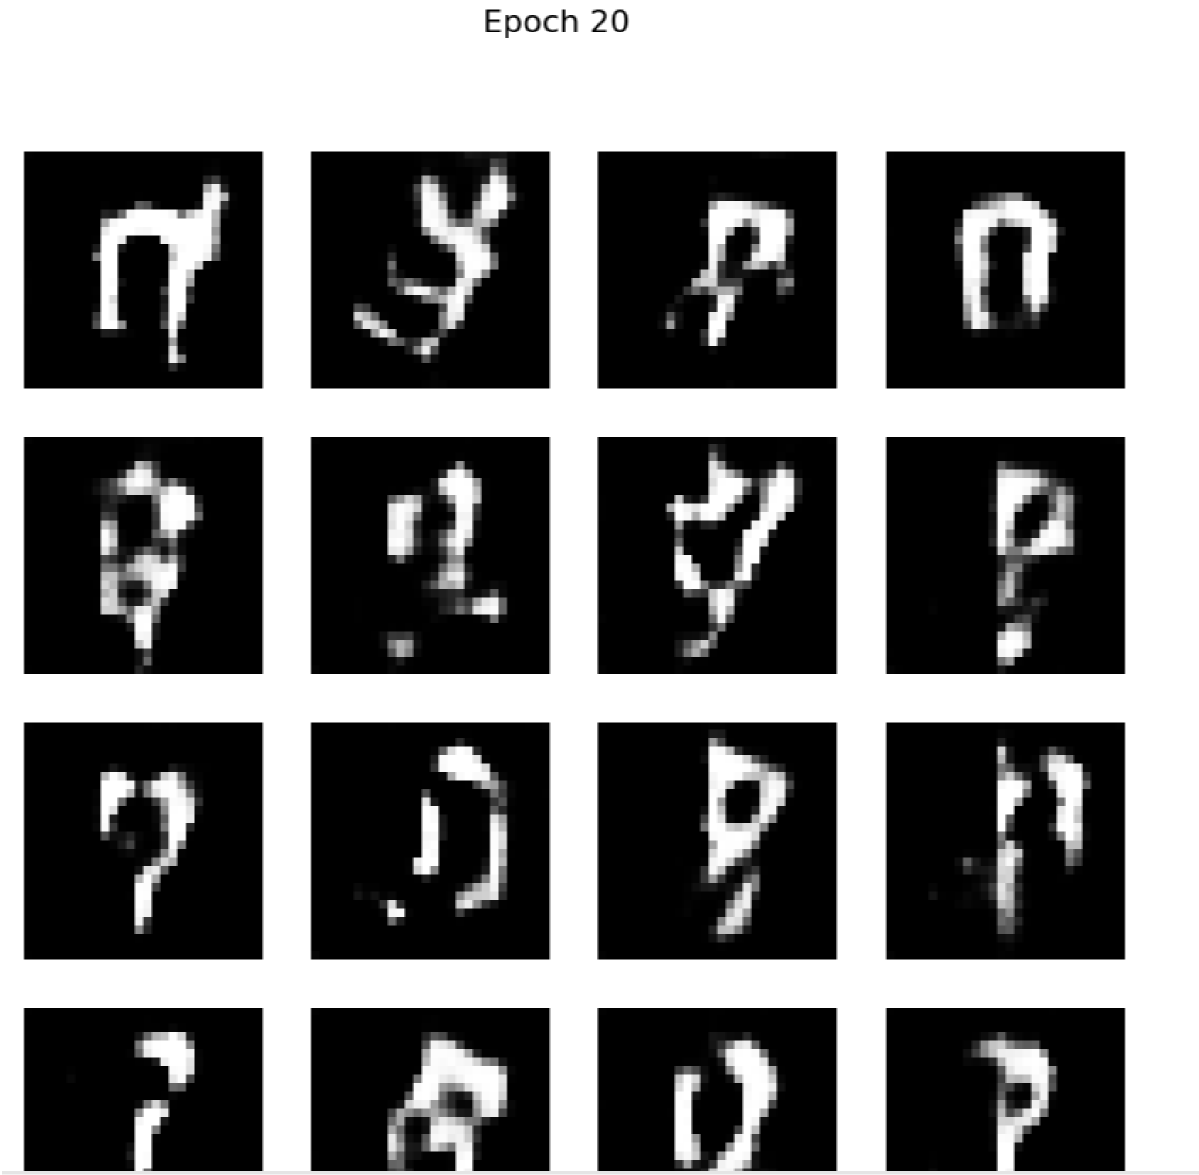
--- Training complete. Generating final images. ---
```



RESULT:

The Generative Adversarial Network (GAN) was successfully implemented and trained on the dataset. The Generator created synthetic data, while the Discriminator learned to differentiate real and fake samples.

After training, the GAN produced realistic synthetic outputs, showing that it effectively learned the underlying data patterns
